Your final is due by the end of day on 12/23/2016. You should post your solutions to your GitHub account. You are also expected to make a short presentation during our last meeting (3-5 minutes) or post a recording to the board. This project will show off your ability to understand the elements of the class.

You are to register for Kaggle.com (free) and compete in the House Prices: Advanced Regression Techniques competition. <https://www.kaggle.com/c/house-prices-advanced-regression-techniques> . I want you to do the following.

Pick one of the quantitative independent variables from the training data set (train.csv) , and define that variable as X. Pick SalePrice as the dependent variable, and define it as Y for the next analysis.

```
train_orig <- read.csv("train.csv")
train_orig
```

Probability

Calculate as a minimum the below probabilities a through c. Assume the small letter “x” is estimated as the 4th quartile of the X variable, and the small letter “y” is estimated as the 2d quartile of the Y variable. Interpret the meaning of all probabilities.

a $P(X > x \mid Y > y)$ b. $P(X > x, Y > y)$ c. $P(Xy)$

Does splitting the training data in this fashion make them independent? In other words, does $P(XY) = P(X)P(Y)$ or does $P(X|Y) = P(X)$?

By this test they are not independent because part a (.25) \neq part b (.12)

I hope you do not mind. I took a few liberties. In order to get things to graph right I had to make sure I had the same number of observations in each dataset. Therefore I sampled the same number of observations from the fitted distributions as are in the original dataset. Also on the graph I am comparing the original dataset to both a gamma and weibull distribution. I also did both a density graph and histogram. The gamma distribution looks like it has the same mean value but less of a spread than the original distribution. The weibull distribution correctly approximates the spread, but the peak of the mean is not as high or in exactly the same place.

Modeling

Picked a few variables from the Training dataset that looked promising

```
train_orig <- read.csv("https://raw.githubusercontent.com/RaphaelNash/CUNY-DATA-605-CompMath/master/Fin
train <- train_orig[,c("LotArea", "SalePrice" , "OverallQual")]
ggplot(data = train, aes(y=SalePrice, x = LotArea, color = OverallQual )) + geom_point()
```

Looks like a linear model would fit this data very well, however I will look to see what degree polynomial would fit this data best.

```
set.seed(5)
cv.err5 <- numeric()
for ( i in 1:10) {
  glm.fit<-glm(SalePrice ~ poly(LotArea + SalePrice+ OverallQual ,i), data=train)
  cv.err5[i]<-cv.glm(train,glm.fit,K=5)$delta[1]
  glm.fit
}
```

```
degree=1:10
plot(degree,cv.err5,type='b')
```

Looks like a linear model would fit this data quite well

```
ggplot(data=train, aes(LotArea)) + geom_histogram(binwidth = 1000) +xlim(c(0,40000))
```

```
## Warning: Removed 14 rows containing non-finite values (stat_bin).
```

```
ggplot(data=train, aes(SalePrice)) + geom_histogram(binwidth = 10000) +xlim(c(0,500000))
```

```
## Warning: Removed 9 rows containing non-finite values (stat_bin).
```

```
ggplot(data=train, aes(OverallQual)) + geom_histogram(binwidth = 1) +xlim(c(0,10))
```

While the Sale Price and lot area have a long tail, they look relatively normally distributed. Therefore I am going to say that all the variables look normally distributed therefore we can go ahead with the linear regression

```
model <- lm (SalePrice ~ . , data = train)
```

```
summary(model)
```

```

```
plot(model$fitted.values, model$residuals)
```

While lot area and overall quality do have a statistically significant impact on sales price, they only account for 65% of the variance in the sales price. Also the plot of the residuals has the megaphone shape, therefore as the sales price gets higher, the variance increases. In my overall judgement I do not think that this is a good model for this data. I should do more exploratory data analysis and/or try other model types to improve the model.
